Important Instructions to examiners:

1) The answers should be examined by key words and not as word-to-word as given in the model answer scheme.

2) The model answer and the answer written by candidate may vary but the examiner may try to assess the understanding level of the candidate.

3) The language errors such as grammatical, spelling errors should not be given more importance (Not applicable for subject English and Communication Skills.

4) While assessing figures, examiner may give credit for principal components indicated in the figure. The figures drawn by candidate and model answer may vary. The examiner may give credit for any equivalent figure drawn.

5) Credits may be given stepwise for numerical problems. In some cases, the assumed constant values may vary and there may be some difference in the candidate’s answers and model answer.

6) In case of some questions credit may be given by judgement on part of examiner of relevant answer based on candidate’s understanding.

7) For programming language papers, credit may be given to any other program based on equivalent concept.

### 1-d Thermal properties of engineering materials: (any 2)

1. Melting point
2. Specific heat
3. Heat capacity (specific heat capacity)
4. Thermal expansion
5. Thermal conductivity
6. Thermal stability
7. Thermal shock resistance
8. Heat resistance/thermal resistance

### 1-e Engineering applications of ceramics: (any 2)

Ans: Ceramics are used for following engineering applications,

1. Cutting tools and dies
2. Molten metal filters
3. Bearings
4. Sealing rings
5. Bushes
6. Fuel injection components
7. Spark plug insulators
8. Disk brakes and clutches
9. Jet turbine blades
10. Fuel cells
11. Body armour
12. Tank power trains
13. Gas burner nozzles
14. Catalytic converters
15. Catalyst supports
16. Catalyst
17. Heat exchangers
18. Reformers
19. Kiln linings
20. Crucibles for glass making
21. Firebricks for furnace and ovens
22. Cylinder liners
23. Capacitors
24. Resistance heating elements
25. Flow control valves
26. Light emitting diodes, laser diodes
27. Optical communication cables
28. Heat sink for electronic parts
29. Filters
30. Rotors and gears
31. Electrode materials
32. Precise instrument parts
33. Grinding media
34. Ballistic armour
35. Bullet proof vests
36. Thread processing nozzles, oiling nozzles, rollers and twister parts.

1-f  Example of thermosetting polymer with its structure (any 1)

Ans:
1. Nylon
2. Nylon-6
3. Nylon-66

1 mark for name and 1 mark for structure
4. Silicon rubber

5. Urea formaldehyde

6. Phenol formaldehyde
7. Polyester

\[
\text{Poly(bisphenol-A-terephthalate)}
\]

8. Silicones
of carbon content are –

1. Low carbon steel: 0.05 – 0.3 %
2. Medium carbon steel: 0.3 – 0.5 %
3. High carbon steel: 0.5 – 2 %

<td>The microstructure of a material influences physical properties of the material such as strength, toughness, wear resistance etc.</td>
</tr>
</tbody>
</table>

2-b **Definition:**

i) **Melting point** –

- The melting point of a material is the temperature at which it changes
state from solid to liquid at normal atmospheric pressure.

- The temperature at which a solid material melts to become a liquid at normal atmospheric pressure.

(ii) **Specific heat** –
- The specific heat of a material is the amount of heat energy per unit mass required to raise the temperature of the material by one degree Celsius.

(iii) **Heat capacity** –
- Heat capacity is the quantity of heat energy needed to raise the temperature of a specific material by one degree Celsius.
- Heat capacity is the ratio of the quantity of heat energy transferred to a material and the resultant temperature rise.

(iv) **Dielectric constant** –
- The dielectric constant is the ratio of the permittivity of a material to the permittivity of free space.
- It is an amount measuring the ability of a material to store electrical in an electric field.

<table>
<thead>
<tr>
<th>2-c</th>
<th><strong>Definition:</strong></th>
</tr>
</thead>
</table>

**Impact strength** –
- The resistance of a material to fracture by a blow, expressed in terms of the amount of energy absorbed before fracture.
- The impact strength is the ability of a material to absorb shock and impact energy without breaking/fracture.

**Compressive strength** –
- The compressive strength is the ability of a material to resist squeezing (compressive) load without fracture.
### Subject Title: Chemistry of Engineering materials

**Subject code:** 22233

- It is the maximum compressive stress that a material can sustain without fracture/failure, under gradually applied load.

<table>
<thead>
<tr>
<th>2-d</th>
<th><strong>Corrosion.</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Definition:</strong></td>

<tr>
<td>- Corrosion is the gradual deterioration or destruction of materials (usually metals and alloys) by chemical or electrochemical reactions with its environment.</td>
<td></td>
</tr>
<tr>
<td>- Corrosion is defined as the gradual deterioration or destruction of a metal by chemical or electrochemical reactions with its environment.</td>
<td></td>
</tr>
<tr>
<td>- Any process of deterioration and consequent loss of a solid metallic material through undesired chemical or electrochemical attack by its environment starting at the surface.</td>
<td></td>
</tr>
</tbody>
</table>

#### Factors affecting rate of corrosion –

The factors affecting rate of corrosion are:

A) Nature of the material (metal dependent factors) -

1) Position of the metal in the electrochemical or galvanic series
2) Purity of the metal
3) Surface of the metal
4) Relative area of cathodic and anodic part (anodeto cathode area ratio)
5) Nature of the oxide film
6) Solubility of the corrosion product
7) Physical state of the metal
8) Volatility of the corrosion product

B) Nature of the environment (environment dependent factors) –

一半分数，每空一分

2
1) Temperature of the environment
2) pH of the environment
3) Humidity of the environment/presence of the moisture in the environment
4) Presence of impurities in the environment
5) Amount of oxygen in the environment
6) Nature of anions and cations present in the environment
7) Presence of suspended particles in the environment

2-e Definition:

1) Ductility
   - Ductility is the ability of a material to be deformed plastically without fracture under tensile strength.
   - Ductility is the property of material by which materials can be drawn out into fine wire without fracture.

2) Plasticity
   - The ability of a material to deform under load and retain its new shape when the load is removed.

3) Hardness strength
   - It is the resistance of a material to plastic deformation-penetration, scratching, abrasion or cutting.
   - The ability of a material to resist wear or abrasion and resist penetration.

3 Any three 12

3-b **Classification of metals:**

Metals:

1. Ferrous. Example: cast iron, stainless steel
Classification of non metals:
1. Plastic
2. Rubber
3. Glass
4. Ceramics
   e.g. wood, asbestos etc.

Uses of metals:
Metals are used for MOC in steam boiler and steam pipeline ½ mark each for any 2
It is used in storage and transporting each for any 2
It is used for distillation column, storage tank, pump, pipe etc.

Uses of non metals:
Non-metals are used for gaskets. ½ mark each for any 2
It is used for seals, bushes, glands etc.
Used for vessel and reaction kettle lining. Etc.

3-c Corrosion in alkaline medium:
Cathodic reaction is: absorption of oxygen
\[ O_2 + 2H_2O + 4e^- \rightarrow 4OH^- \]
Corrosion is less in alkaline medium
Example of alkaline medium is NaCl solution,
e.g.
a piece of iron is immersed in sodium chloride solution
\[ Fe \rightarrow Fe^{2+} + 2e^- \]
\[ NaCl \rightarrow Na^+ + Cl^- \]
\[ \frac{1}{2}O_2 + H_2O + 2e^- \rightarrow 2OH^- \]
\[ Na^+ + OH^- \rightarrow NaOH \]
\[ Fe^{2+} + 2Cl^- \rightarrow FeCl_2 \]

3-d Composition of SS-304:
18 – 20 % Cr, 8 – 10.5 % Ni, 0.08 % max C, small amount of Mn, Si, P, S and the balance is Fe.

**Properties:**
- Density= 8000 Kg/ cu. m
- MP. : 1450 deg. C
- Thermal conductivity: 16.2 W/(mK)
- Good weld ability
- Good heat resistance
- Good drawing and forming properties

### 4 Any three 12

#### 4-a Crystal structure of glass by Bragg’s law:

The general relationship between the wavelength of the incident x ray, angle of incidence and spacing between the crystal planes of atoms is known as Bragg’s law, expressed mathematically as

\[ 2d \sin \theta = n\lambda \]

Where \( n \) is an integer, \( \lambda \) is the wavelength of the incident x ray, \( d \) is the interplanar spacing of the crystal or distance between the layers of atoms and \( \theta \) is the angle of incidence.

1. Consider that the x ray of wavelength \( \lambda \) is incident on a crystal at an angle \( \theta \). The incident rays AB and PQ after reflection from the crystal
lattice planes \( Y \) and \( Z \) travel along \( BC \) and \( QR \)

2. Let the spacing between the crystal lattice planes of atoms be \( d \)

3. Draw perpendiculars \( BD \) and \( BE \) from point \( B \) on \( PQ \) and \( QR \)
   respectively. \( BD \) and \( BE \) are the perpendiculars from point \( B \) on lines \( PQ \) and \( PR \) respectively.

4. Thus the path difference between the two waves \( ABC \) and \( PQR \) is \( DQ + QE \). The path of the wave \( PQR \) is longer than the path of the wave \( ABC \) by \( DQ+QE \).

   In the \( \Delta DBQ \), \( \sin \theta = \frac{DQ}{BQ} \)
   Therefore \( DQ = BQ \sin \theta \)

   In the \( \Delta EBQ \), \( \sin \theta = \frac{QE}{BQ} \)
   Therefore \( QE = BQ \sin \theta \)

   Path difference between two rays = \( DQ + QE \)
   \[ = BQ \sin \theta + BQ \sin \theta = 2BQ \sin \theta \]
   \[ = 2d \sin \theta \quad \text{since} \; BQ = d \]

   If the path difference \( 2d \sin \theta \) is equal to the integral multiple of wave length of x ray, i.e. \( n\lambda \), then constructive interference will occur between the reflected rays and they will reinforce each other and consequently the intensity of reflected beam is maximum.

   Thus, for constructive interference to occur:

   \[ 2d \sin \theta = n\lambda \]

   This is known as Bragg’s law.
4-b **Chemical reactivity of iron with air:**
Chemical reactivity is the ability of a material to combine with the other materials.
Chemical reactivity of iron / mild steel (MS) with air
MS react with air to form iron oxide, Fe$_2$O$_3$. MS react with oxygen from air in the presence of moisture or dissolved oxygen from water to produce hydrated iron oxide Fe$_2$O$_3$.xH$_2$O (called brown rust). The oxide film is formed is non-protective and it flake-off from the surface thereby exposing the fresh metal surface for further reaction with air and water.

4-c **Q = m x Cp x(T$_2$-T$_1$)**
\[
= 50g \times 4.18 \text{ J/gK} \times (373 - 273) \text{ K}
= 20900 \text{ joules}
\]

4-d **Classification of ceramics:**
1. **Glasses:**
   Glasses
   Ceramic glasses

5-b Industrial importance of:

i) Silicon carbide:
   1. It is used in car brakes and clutches.
   2. Ceramic plates in bulletproof vests
   3. Bearings
   4. Semiconductors wafer processing equipment
   5. Light emitting diode
   6. Cutting tools and burner nozzles.

ii) Aluminium oxide:
   1. Bearing liners and seals
   2. Cutting tools
   3. Artificial bones and teeth
   4. Engine and turbine parts
   5. Thermometry sensors
### Classification of alloy steels

Based on its composition:

1) Simple alloy steels:
   - It is the alloy steel containing one alloying element e.g., nickel steel

2) Quaternary alloy steel:
   - It is the alloy steel containing two alloying elements e.g., chromium and vanadium

3) Complex alloy steel:
   - It is the alloy steel containing more than two alloying elements e.g., High speed tool steel

### Prevention and control of corrosion:

1. Material selection and choice of materials
2. Proper design and fabrication of components
3. Use of high purity metals: The impurities present in a metal cause heterogeneity and form tiny electrochemical cells with rest of the metal. Due to this, metal undergoes corrosion at the region where impurities are present. Pure metal does not corrode.
4. Specific heat treatment
5. Modification of corrosion environment
6. Use of alloying: Corrosion resistance of many metals can be increased by alloying them with suitable alloying elements.
7. Use of inhibitors: Inhibitors are organic chemicals which are added in small amounts to a corrosive medium in order to reduce its corrosive effect. Usually they form and maintain a protective film on the metal surface and thus acts as a barrier for further corrosion.
8. Cathodic protection (electrochemical protection): In this, the metal is forced
to behave like a cathode thus protecting it from corrosion. This is achieved by supplying electrons to the metal surface to be protected. Addition of electrons to the metal suppresses its dissolution into metal ions. Different types are:

- Sacrificial anodic method
- Impressed current method

9. Use of protective surface coatings: Protective coatings provide a continuous physical barrier between the surface to be protected and the environment. These are classified as:

- Metallic coatings
- Inorganic coatings
- Organic coatings

### 6-b Effect on iron:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>i)</td>
<td>Copper: it improves the resistance to atmospheric corrosion. It strengthens steel. It may be added to improve formability. It improves pains adhesion</td>
</tr>
<tr>
<td>ii)</td>
<td>Phosphorus: it is considered as the undesired impurities in steel because of its embrittling effect. It improves strength but at the same time decrease the ductility. It is upto 0.04 % by weight.</td>
</tr>
<tr>
<td>iii)</td>
<td>Manganese: it increase tensile strength, abrasion resistance, hardenability and toughness. It decrease weldability.</td>
</tr>
</tbody>
</table>

### 6-c Cladding mechanism:

Cladding is the bonding together of dissimilar metals. It is different from fusion welding or gluing as a method to fasten the metals together. Cladding is often achieved by extruding two metals through a die as well as pressing or rolling sheets together under high pressure.

Laser cladding is a method of depositing material by which a powdered or wire feedstock material is melted and consolidated by use of a laser in order to coat part of a substrate or fabricate a near-net shape part.
It is often used to improve mechanical properties or increase corrosion resistance, repair worn out parts and fabricate metal matrix composites.

**Process:**

The powder used in laser cladding is normally of a metallic nature, and is injected into the system by either coaxial or lateral nozzles. The interaction of the metallic powder stream and the laser causes melting to occur, and is known as the melt pool. This is deposited onto a substrate; moving the substrate allows the melt pool to solidify and thus produces a track of solid metal. This is the most common technique, however some processes involve moving the laser/nozzle assembly over a stationary substrate to produce solidified tracks.

**Advantages**

- Best technique for coating any shape.
- Particular dispositions for repairing parts.
- Most suited technique for graded material application.
- Well adapted for near-net-shape manufacturing.
- Low dilution between track and substrate
- Low deformation of the substrate and small heat affected zone.
- High cooling rate.
- A lot of material flexibility (metal, ceramic, even polymer).
- Built part is free of crack and porosity.
- Compact technology.
